AI and Robotics

Lesson 2a: Components of a Robotic Agent

Sarah Keren

The Taub Faculty of Computer Science
Technion - Israel Institute of Technology

Table of contents

1. Components of a Robotic Agent

2. Robot State

Components of a Robotic Agent

Reminder: Autonomy

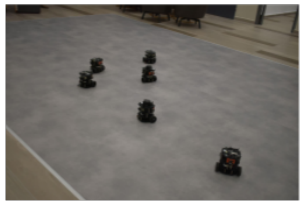

- Action (Actuation)
  - Locomotion: wheels (e.g., differential drives)
  - Manipulation: arms, grippers, etc.
- Perception (Sensors)
  - Proprioception (internal: IMU (inertial measurement unit), encoders , etc,)
  - Exteroception (external: cameras, scanners)
- Cognition (Control)
  - From reactive to proactive
  - From finite state machines to cognitive robotics

Many Types of Robots

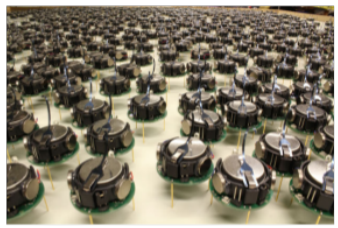

Components of a Robotic Agents

Sensors

Controllers

Actuators

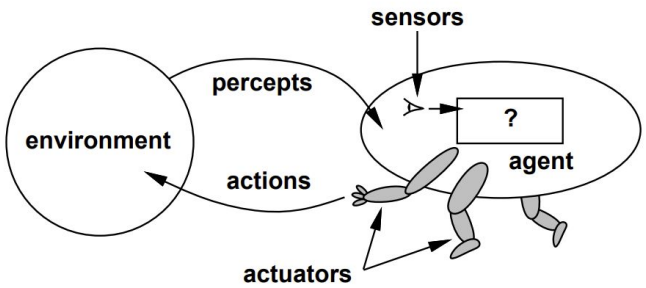

Components of a Robotic Agent

Robot State

state estimation

decision making

motion control

Actuators

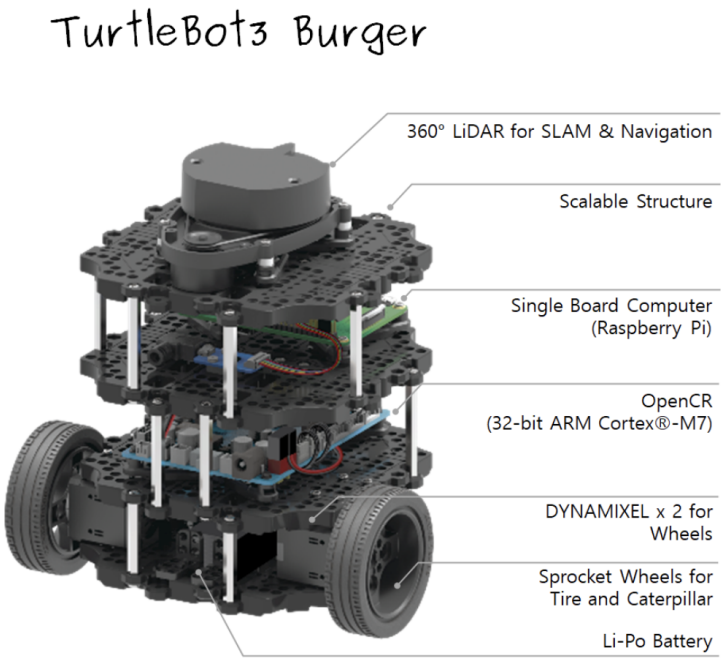

- Actuators control movements within machines.
- There are various kinds of actuators that
  - produce varying motions (linear or rotary)
  - use different power sources
    - hydraulic (with a fluid-filled cylinder)
    - pneumatic (using pressurised gases)
    - electric (popular in robotics)

The UR actuators

- The UR robot (by Universal Robots) is a 6-degree-of-freedom (6-DoF) collaborative robotic arm.
- Its actuators are the electric servo motors integrated into each of its six joints.

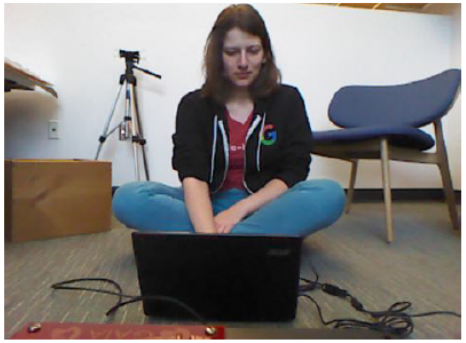

Sensors

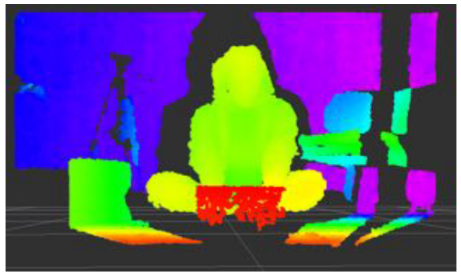

- Used to estimate the robot's condition and environment and passed to the controller to decide how to act.
- Generally classified into two groups:
  - **Internal sensors**
    - obtain the information about the robot itself (e.g., position, velocity, acceleration, motor torque sensor, etc)
  - **External sensors**
    - gather information from the surrounding environment (e.g., cameras, laser range finder, contact and proximity sensors, and force sensors)

Sensors: Vision

Many vision options: color, depth, video, and more.

Vision

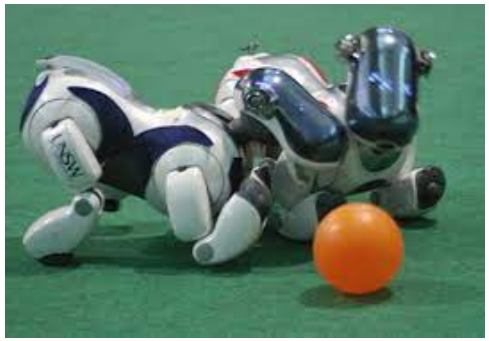

Why is vision challenging?

Vision

Why is vision challenging ?

The turtlebot3 burger sensors

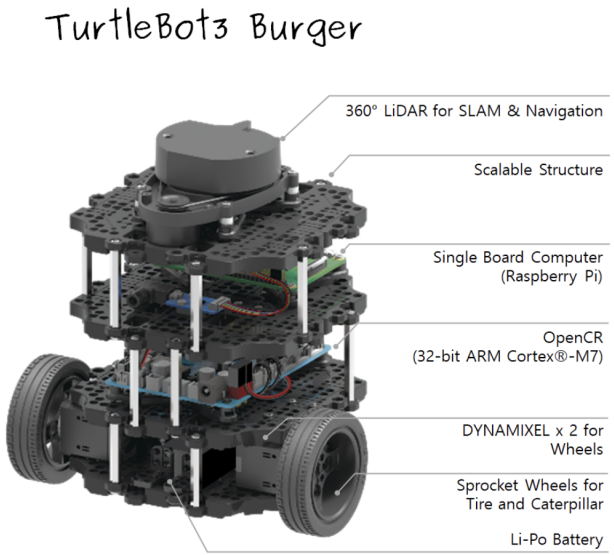

- 360 degree Laser Distance Sensor - Laser Distance Sensor LDS-01
- Gyroscope - measures or maintains orientation and angular velocity.
- Accelerometer - measures acceleration.
- Magnetometer 3 Axis - measures magnetic induction (magnetic field intensity),

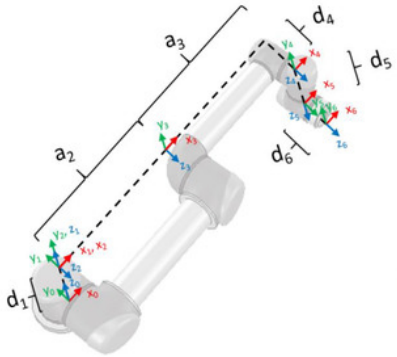

The UR Sensors

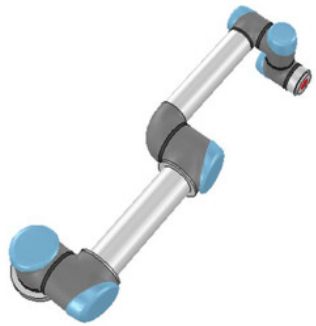

- Each actuator includes:
  - Absolute encoders - for joint angle measurement
  - Torque sensors - for collision detection and compliant motion
  - Temperature sensors- for thermal protection

Control and Decision-Making

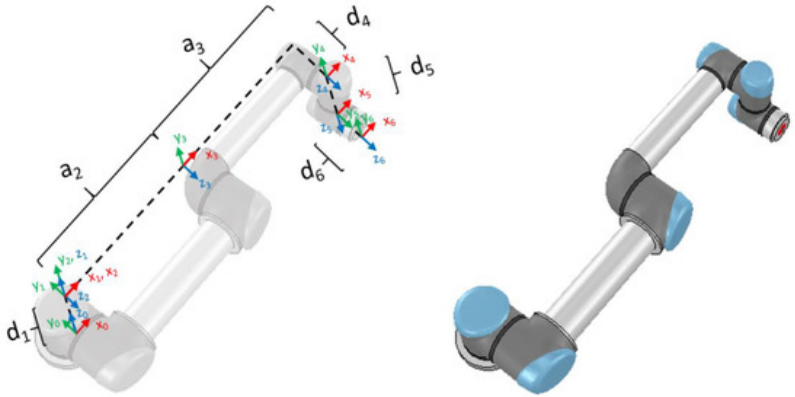

- Varies according to setting and objectives
- Highly influenced by uncertainty and the way it is accounted for
- A major focus of this course

Robot State

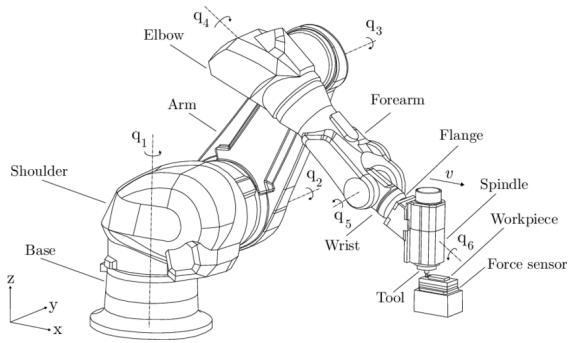

Configuration

- The **configuration** of a robot is a complete specification of the position of every point of the robot.
- A configuration q is **collision-free**, or free, if the robot placed at q does not intersect any obstacles.

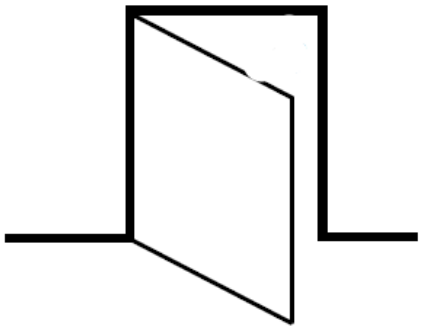

Degrees of Freedom (dof)

- The **degrees of freedom (dof)** of a robot are the minimum number n of real-valued coordinates needed to represent the configuration of a robot.
- A mechanism is typically constructed by connecting rigid bodies, called **links**, together by means of **joints**, so that relative motion between adjacent links becomes possible.
- **Actuation** of the joints, typically by electric motors, then causes the robot to move and exert forces in desired ways.
- dof typically refers to the number of movable joints of a robot.

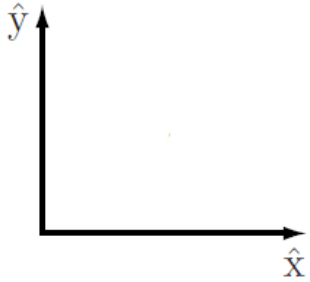

Degrees of Freedom (dof)

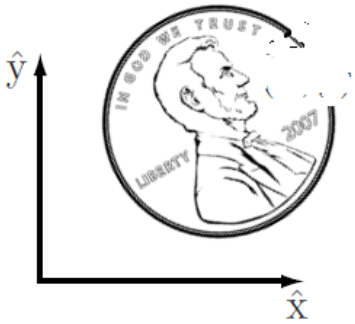

What's the dof ?

(a)

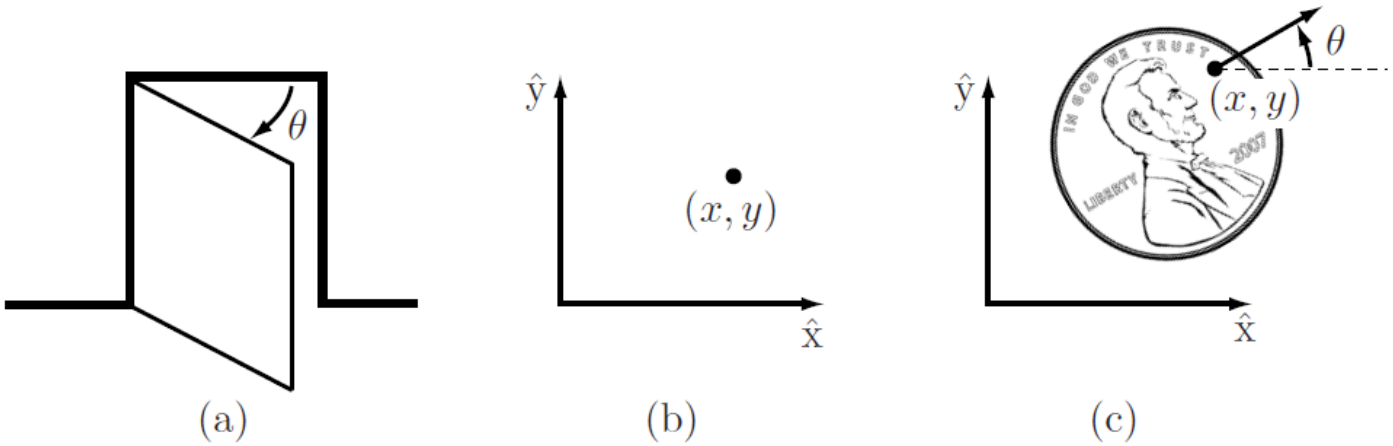

(b)

(c)

Degrees of Freedom (dof)

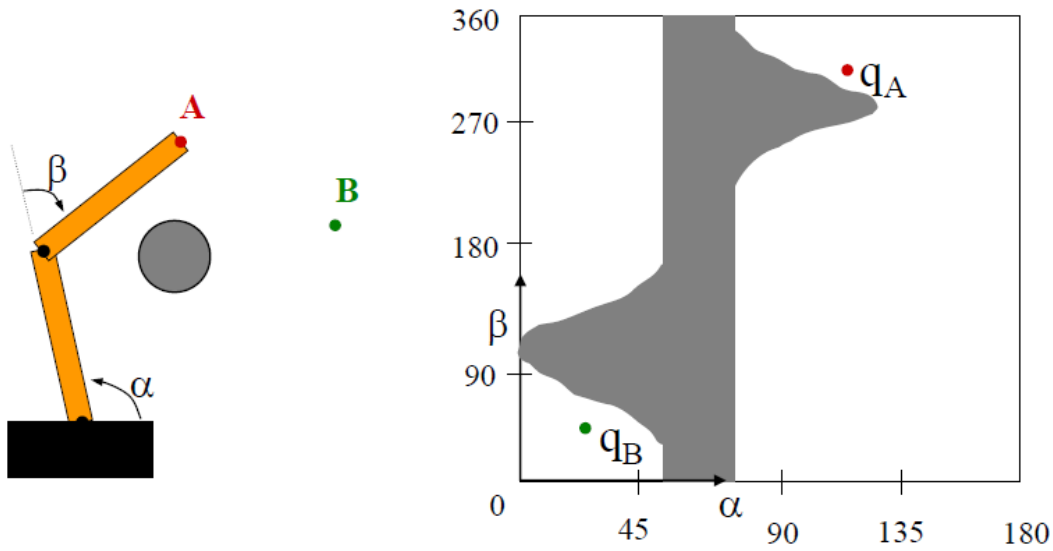

The configuration of a door is described by the angle θ (b) The configuration of a point in a plane is described by coordinates (x, y). (c) The configuration of a coin on a table is described by (x, y, θ), where θ defines the direction in which Abraham Lincoln is looking.

Configuration space, work space and task space

We are going to consider three space representations:

- The **workspace** is a specification of the robot's possible positions in the environment.
- The **configuration space (C-space)** is a specification of the robot's attainable positions in the environment. It is the n-dimensional space containing all possible configurations of the robot.
- The **task space** is the space in which the robot's task can be naturally expressed.

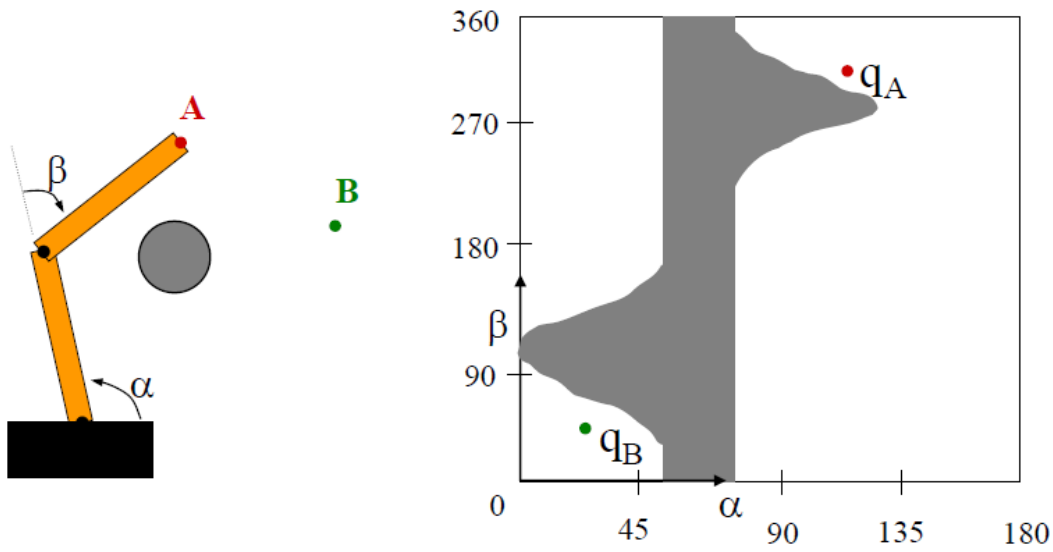

Configuration space, work space, and task space: example

- This robot arm has two joints that move independently.
- Moving these joints alters the coordinates of the elbow and the gripper.

What's the workspace, configuration space and task space here ?

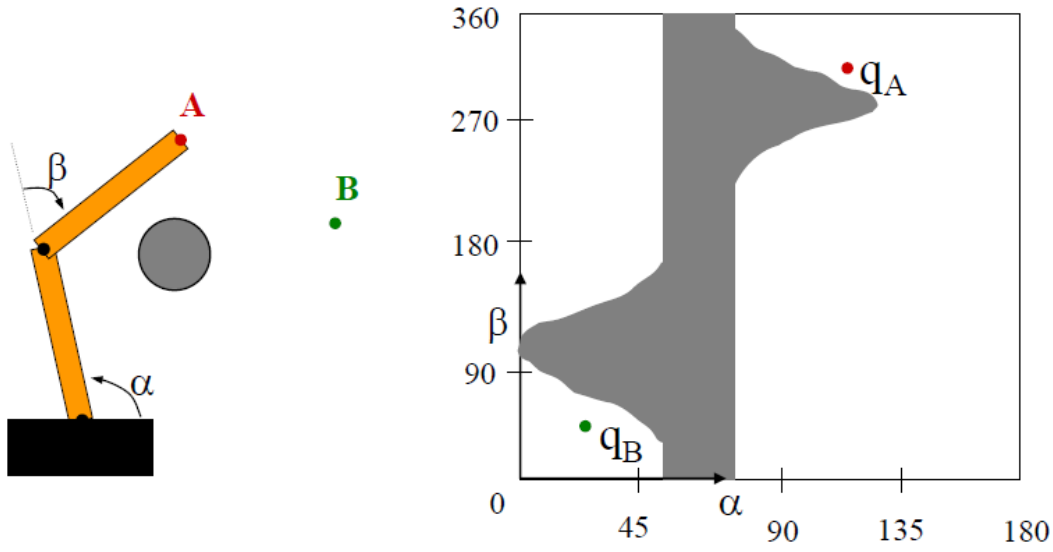

Configuration space, work space, and task space

The **workspace** is a specification of the configurations that the end-effector of the robot can reach.

Here, the **workspace** is defined by the coordinates of the robot that are specified in the same coordinate system of the world it's manipulating (left image).

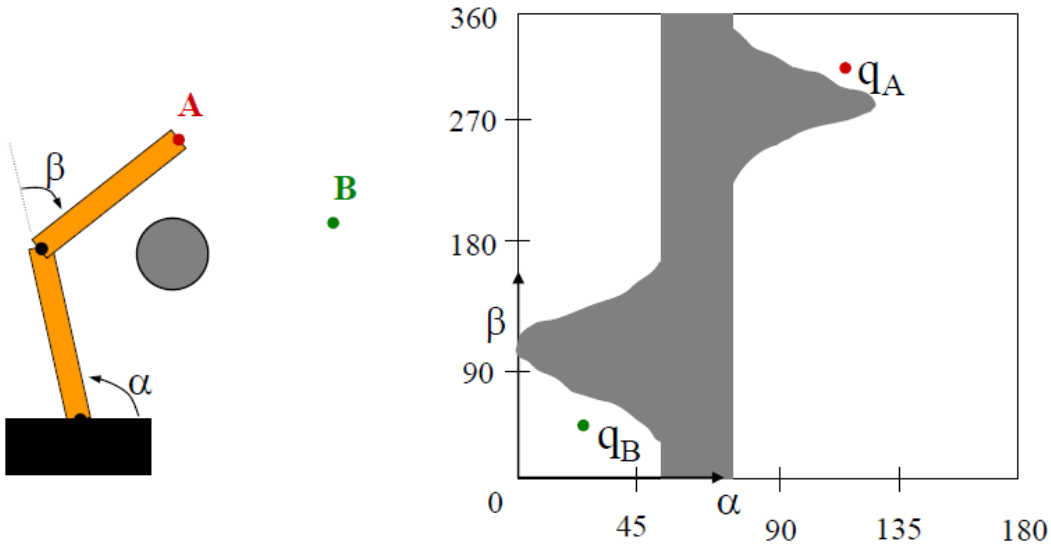

Configuration space, work space, and task space

- The configuration space (C-space) $\mathcal{C}$ is the n-dimensional space containing all possible assignments to the DOFs of the robot.
- Here, the C-space is defined by α and β and is represented in the right figure.

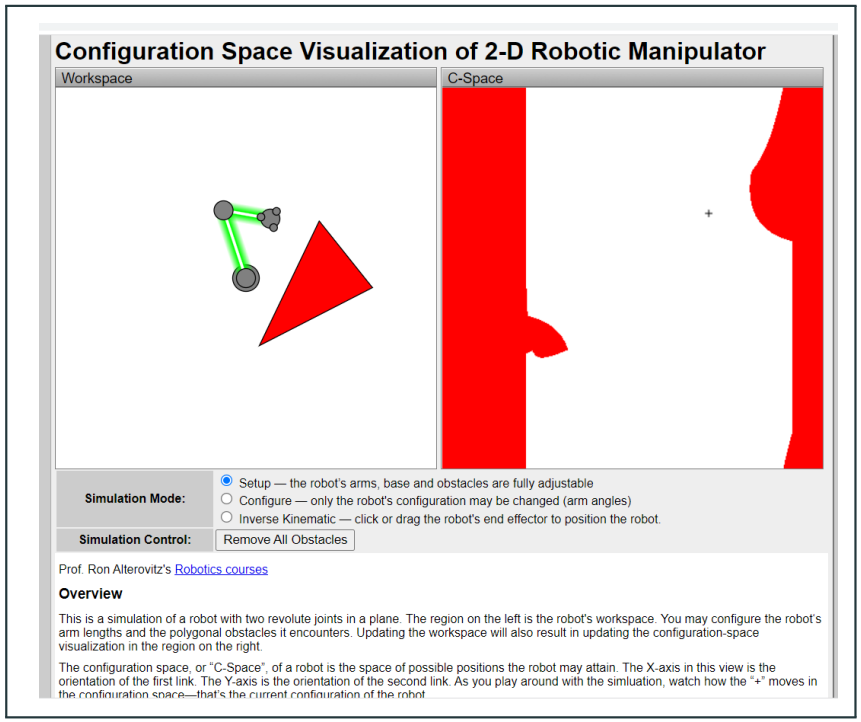

Can the robot get from A to B ?

Configuration space, work space, and task space

- The **task space** is a space in which the robot's task can be naturally expressed.
- For example, if the robot's task is to plot with a pen on a piece of paper, the task space would be R^2.
- The decision of how to define the task space is driven by the task, independently of the robot.

Configuration space, work space, and task space
